REPORT ON FINAL DETERMINATION OF
OPERATING SAFE YIELD
FOR 2025-26 THROUGH 2029-30**

May 7, 2025

SPECIAL INTRODUCTION

For fiscal year 2024-25, the Basin is currently experiencing 36 percent of average rainfall and the State is currently experiencing 93 percent of normal snowfall and 110 percent of normal rainfall. The State Water Project (SWP) Allocation for 2025 is 50 percent, as of May. In addition, due to an unprecedented long-term drought since 2005, there was strong conservation messaging throughout the Basin to help the Basin water levels from declining further, along with 2022 and 2023 local wet conditions. The conservation messaging and wet conditions resulted in the Basin experiencing production as low as 168,000 acre-feet in fiscal year 2022-23, which is a historical low since the adjudication. It appears fiscal year 2024-25 production is trending to be around 190,000 acre-feet, even with below average rainfall. In addition to conservation messaging, the Watermaster has made significant changes to Basin management (including Water Resources Development Assessment (RDA)) to help supplement the significant reduction in local water supply for Basin replenishment. During this time, the Watermaster reduced and held the Operating Safe Yield (OSY) at 150,000 acre-feet for the last ten (10) consecutive years, which is unprecedented. The Engineer has stated, "...the Watermaster should consider maintaining the OSY at no more than 150,000 acre-feet until such times as the operational elevation at the Key Well is significantly above elevation 200 feet...", and hydrologic conditions demonstrate an increasing Key Well elevation, significant storage in canyon reservoirs for replenishment, and adequate imported water supply availability. Last year was the first time since that 10-year period the Watermaster increased the OSY to 160,000 acre-feet. The Watermaster has used the RDA and OSY as the primary "tools" for Basin water supply management.

INTRODUCTION

Operating Safe Yield is the quantity of water which the Main San Gabriel Basin Watermaster (Watermaster) determines may be pumped from the Main San Gabriel Basin (Basin) in a fiscal year, free of Replacement Water assessments. In

accordance with Section 43 of the amended Main San Gabriel Basin Judgment¹, Watermaster at its regular meeting in May of each year determines the Operating Safe Yield applicable to the succeeding fiscal year and estimates the Operating Safe Yield for the next succeeding four fiscal years.

A Report on the "Preliminary Determination of Operating Safe Yield" is submitted by its Engineer to Watermaster at its regular meeting in April each year. On acceptance of that Report by Watermaster, a copy is distributed to each Pumper and Integrated Producer at least 10 days prior to a hearing, which is held at the regular meeting of Watermaster in May each year. Objections, comments or suggested modifications to the preliminary Operating Safe Yield are considered by Watermaster at that hearing and Watermaster, through vote of its Board members, adopts the final Operating Safe Yield.

BASIN OPERATING CRITERIA

Section 42 of the amended Judgment states in part, "... Watermaster shall recharge Replacement Water in accordance with the Watermaster Operating Criteria and, insofar as practicable, to maintain the water level at the Key Well above Elevation two hundred (200)." Replacement Water is defined in Section 10 (cc) of the amended Judgment as "Water purchased by Watermaster to replace: (1) Production in excess of a Pumper's Share of Operating Safe Yield; (2) The consumptive use portion resulting from the exercise of an Overlying Right; and (3) Production in excess of a Diverter's right to Divert for Direct Use". Producers and Responsible Agencies, through Watermaster, are allowed to deliver Supplemental Water into their respective Cyclic Storage accounts as a pre-delivery of Replacement Water. Furthermore, as a result of recent significant local drought conditions (see Appendix A) the Watermaster took unprecedented actions to supplement local water supplies, and, as part of 2012 Amendments to the Judgment, Watermaster may make deliveries of Supplemental Water to augment the lack of local water replenishment through the Water Resources Development Assessment (RDA) stormwater augmentation program. The Operating Safe Yield, using Replacement Water, and delivery of Supplemental Water, using the RDA, are the primary tools being used for management of Basin groundwater levels.

The Operating Safe Yield, which is established in May of each year, along with the prior year's carryover rights and the Diversion component of Integrated Producers, results in a Replacement Water requirement (net of any withdrawals from Producer Cyclic Storage accounts) that is delivered (at the earliest) in October of the second fiscal year, a span of about 17 months, and possibly not until the following June, a span of 26 months, assuming imported Supplemental Water is available. In the time frame between when the Operating Safe Yield is established and Supplemental Water is actually delivered, the actual hydrologic conditions experienced may have had

¹ Upper San Gabriel Valley Municipal Water District vs. City of Alhambra, et al., Case No. 924128, Los Angeles County, as amended June 21, 2012.

significant impacts on the Basin groundwater levels. Therefore, it is prudent to conservatively manage the Basin groundwater levels and assure that Replacement Water assessment funds and RDA funds are appropriately collected and available for the purchase of available Supplemental Water to provide for Basin replenishment. The producer's significant purchase of Cyclic Storage water in advance of a Replacement Water obligation has helped to manage the "17-month" time delay for the actual delivery of Replacement water. This Report is for the management of Basin groundwater levels using the Replacement Water management tool.

Watermaster evaluates numerous factors when determining the Operating Safe Yield. The most critical factors are the provisions of the Judgment and the current and projected groundwater elevation at the Baldwin Park Key Well (Key Well), which represents the water stored in the Basin. Importantly, Watermaster focuses on the "operational" groundwater elevation at the Key Well (which excludes the impacts of Supplemental Water held in all Cyclic Storage accounts).

Figure 1 shows the projected Key Well elevation through the end of this fiscal year 2024-25 (June 30, 2025) and next fiscal year 2025-26 (June 30, 2026). Figure 1 assumes MWD imported water deliveries of about 100,000 acre-feet starting spring 2025. The projection also assumes the delivery and replenishment of local water, and the return of normal percolation rates at SFSG's. Figure 1 shows two lines, one is the "measured" Key Well elevation and the second is the "operational" Key Well elevation (only local water and delivered RDA water, and no Cyclic Storage water). The "operational" Key Well elevation is used in determining the OSY.

Figure 1 shows a projection of the Key Well elevation to June 2026, assuming the availability of imported water through calendar year 2025 of about 100,000 acre-feet and (essentially) worst-case local conditions for fiscal year 2025-26 (dry year and production of 190,000 acre-feet). The projected "operational" Key Well elevation (only local water and delivered RDA water, and no Cyclic Storage water) in June 2025 is projected to be about 216 feet and further decrease in June 2026 to about 202 feet. In addition, the projected Key Well elevation "measured" in June 2025 is about 241 feet and in June 2026 is about 234 feet.

Figure 2 shows the measured groundwater elevation at the Key Well, which includes stored Supplemental Water (Cyclic Storage and the initial Water Resource Development Assessment deliveries to Cyclic Storage) and the operational groundwater elevation at the Key Well, which is used to characterize "natural" groundwater elevations for the purposes of establishing an Operating Safe Yield. However, for the purpose of this Report, the measured Key Well elevation is referenced throughout.

Figure 3 shows the Key Well elevation and the relationship between the "measured" water level, the natural water level with only RDA water, and the natural water level (excludes RDA water and Cyclic Storage). Watermaster also reviews historical and current hydrologic conditions within the Basin, such as rainfall, storage

of local runoff in surface reservoirs and conservation of local runoff; the availability of Supplemental Water; the quantity of water in Cyclic Storage; Carry-over Rights; and other information. Presented in Table 1 is the historical record of the annual Operating Safe Yield, Carry-over Rights, Lost Carry-over Rights, Production Rights, Water Production, and Replacement Water Requirement for each year of Watermaster operations beginning with fiscal year 1973-74.

Stormwater Augmentation – Water Resources Development Assessment

During fiscal year 2015-16, the Watermaster developed a “RDA Stormwater Augmentation Program,” whereby Watermaster uses its Water Resource Development Assessment (RDA II) to purchase available untreated imported water to supplement the shortage of local stormwater replenishment (discussed in detail in the following section). Consequently, once the Stormwater Augmentation Program water is delivered to the Basin, and paid for, it is considered to be a supplement to “local water and available to all Basin pumpers,” but not Supplemental Water. As a result of just the RDA programs (includes all RDA actual water deliveries, including RDA water not yet paid for), Watermaster and the Producers have added over 225,000 acre-feet of replenishment water and increased the elevation of the Baldwin Park Key Well by about 38 feet, as shown in Figure 3. The RDA is the second “tool” in addition to OSY, the Watermaster has to manage Basin water levels and Basin storage. Other Watermaster and Producer actions have also contributed to maintaining the Basin water supply reliability.

MWD Pre-Delivery Agreement

Under the MWD Pre-Delivery Agreement, MWD, Upper District and Watermaster entered into an Agreement to coordinate large amounts of delivery (up to 200,000 acre-feet) into MWD’s Cyclic Storage account. Upper District and Watermaster have up to ten years to purchase that water. At a minimum, MWD requires an annual purchase each year. The purpose of the MWD Pre-Delivery Agreement is when water is available in the SWP Allocation (around 30-35%), MWD would like to deliver as much water as possible in order to prepare for the next drought conditions, when MWD may not deliver Supplemental Water to the Basin. This potential MWD pre-delivery program is predicated on Watermaster managing the Basin so that, when the MWD replenishment supply interruption occurs, the pre-delivered water will be stored in the Basin and available for pumping. Upper District and MWD agreed that the payment schedule for the purchase of water delivered will be over five to ten years. In order to fund these purchases every year, Watermaster uses funds from Replacement Water/Cyclic Storage orders and the RDA from Upper District. Currently, there is about 88,000 acre-feet in MWD’s Cyclic Storage under the Pre-Delivery Agreement. To ensure funds are available each year, the OSY would need to be set in order to create a Replacement Water/Cyclic Storage requirement (i.e., setting a low OSY creates more Replacement Water/Cyclic Storage requirement). If there are not enough funds due to increasing the OSY, more RDA water would need to be purchased to make up the difference. This is accomplished

by increasing the RDA assessment. This is how both OSY and RDA are used as “tools” to manage Basin water levels and Basin storage.

BASIN CONDITIONS - GROUNDWATER ELEVATIONS

Exhibit H, Section 2 of the amended Judgment states in part “Watermaster in determining Operating Safe Yield and the importation of Replacement Water shall be guided by water level elevations in the Basin.” The following describes the groundwater elevation at the Baldwin Park Key Well.

Baldwin Park Key Well

The Key Well is located in the central portion of the Basin, as shown in Plate 1. It has been successfully used to generally represent basin-wide groundwater elevation trends. A one-foot groundwater elevation change at the Key Well is estimated to represent approximately 8,000 acre-feet of water in storage, under normal conditions (Basin operating conditions). Figure 4 is a hydrograph showing the groundwater elevation at the Key Well and annual rainfall at San Gabriel Dam since October 1, 1937. The highest groundwater elevation at the Key Well, since entry of the Judgment, occurred on July 20, 1983 at 295.3 feet at which time 9,900 acre-feet (about one foot) were in Cyclic Storage. The historical low groundwater elevation at the Key Well, since entry of the Judgment, occurred on November 21, 2018 at 169.4 feet at which time 161,000 acre-feet (about 20 feet) were in Cyclic Storage. Without Cyclic Storage, the groundwater elevation at the Key Well would have been about 150 feet on November 21, 2018. Subsequently, the groundwater elevation rose above 210 feet, but again the long-term drought caused the groundwater elevation to decline to nearly 175 feet in 2022. Due to a combination of spreading imported water, recent local storm events and conservation efforts, the Key Well increased by 68 feet since 2022.

Fiscal year 2024-25 is proving to be a below-normal rainfall year. On May 2, 2025, the groundwater elevation at the Key Well was 244.3 feet, at which time about 195,000 acre-feet (about 24 feet) were in Cyclic Storage. Without Cyclic Storage, the Key Well elevation would have been about 220.0 feet on May 2, 2025 (“Operational” Key Well elevation), as shown on Figure 2.

Thus far during fiscal year 2024-25 (through May 2, 2025), rainfall at Puddingstone Dam has been about 7.01 inches (the long-term annual average through April 30th is about 17.55 inches), which is about 40 percent of long-term average through April. Currently, the Key Well elevation was 244.3 feet on May 2, 2025. Typically, during the Summer and early Fall, the measured groundwater elevation at the Key Well decreases by about 10 feet.

Other “Key Wells”

While the groundwater elevation at the Baldwin Park Key Well has decreased by about 0.4 feet from October 25, 2024 to May 2, 2025, the change in groundwater elevations in other parts of the Basin shows an increase. A well location map showing other “Key Wells” is included as Plate 1 and hydrographs of groundwater elevations at four other wells located throughout the Basin (compared to the measured Baldwin Park Key Well groundwater elevation) are included in Appendix B. San Gabriel County Water District Well 10 is located westerly of the Baldwin Park Key Well, County of Los Angeles Well No. 2947F is located southerly of the Baldwin Park Key Well in the vicinity of Whittier Narrows, Suburban Water Systems Well 155W-2 is located in the vicinity of the Puente Narrows and Valencia Heights Water Company Well No. 5 is located southeasterly of the Baldwin Park Key Well. In general, groundwater elevations at each of the four monitoring wells in the Basin react (both upward and downward) in a comparable but in a delayed and less dramatic manner as the Baldwin Park Key Well. As shown on the hydrographs in Appendix B, the groundwater elevations at these wells generally do not increase as high as the Baldwin Park Key Well during wet periods (with significant groundwater replenishment), but also do not have as significant of a decrease during dry periods with less groundwater replenishment. Significant changes in the water level for the other “Key Wells” are not expected in the near future.

BASIN CONDITIONS - RAINFALL

Rainfall in the San Gabriel River watershed provides direct percolation and typically results in local stormwater runoff which is captured and subsequently percolated in spreading facilities and contributes to Basin replenishment. Precipitation amounts vary throughout the San Gabriel River watershed and typically are highest in the foothills and mountains. Precipitation recorded at San Gabriel Dam, the City of Pasadena and Puddingstone Dam, are described below. The locations of these rainfall stations are shown on Plate 1.

San Gabriel Dam - Station 425B-E

Rainfall at San Gabriel Dam, which is located in the upper watershed and not on the valley floor, was about 10.9 inches for the period July 1, 2024 through April 30, 2025, or about 51 percent of average for that period. Assuming average rainfall for the balance of the year, the annual rainfall is projected to be about 58 percent of average. Figure 5 shows the cumulative rainfall for 1) fiscal years, 2017-18, 2018-19, 2019-20, 2020-21, 2021-22, 2022-23, 2023-24; 2) the period July 2024 through April 2025; and 3) the long-term average rainfall at San Gabriel Dam.

Pasadena City Hall - Station 610B

Rainfall at the Pasadena City Hall was about 8.5 inches for the period July 1, 2024 through April 30, 2025, or about 44 percent of average for that period. Assuming

average rainfall for the balance of the year, the annual rainfall is projected to be about 55 percent of average. Figure 6 shows the cumulative rainfall for 1) fiscal years 2017-18, 2018-19, 2019-20, 2020-21, 2021-22, 2022-23, 2023-24; 2) the period July 2024 through April 2025; and 3) the long-term average rainfall at the Pasadena City Hall.

Puddingstone Dam - Station 96C

Rainfall at Puddingstone Dam was 7.01 inches for the period July 1, 2024 through April 30, 2025, or about 40 percent of average for that period. Assuming average rainfall for the balance of the year, the annual rainfall is projected to be about 50 percent of average. Figure 7 shows the cumulative rainfall for 1) fiscal years 2017-18, 2018-19, 2019-20, 2020-21, 2021-22, 2022-23, 2023-24; 2) the period July 2024 through April 2025; and 3) the long-term average rainfall at Puddingstone Dam.

Precipitation in the San Gabriel River watershed during fiscal year 2024-25, through the end of April 2025 was about 45 percent of average.

BASIN CONDITIONS - LOCAL WATER IN SURFACE STORAGE RESERVOIRS

Local runoff water in surface reservoirs located on streams tributary to the Basin is stored by the DPW. This local runoff water is later released to the San Gabriel River system either for direct delivery to users or for replenishment of the groundwater Basin.

Table 4 shows the maximum reservoir storage capacity and the quantities of water in storage in surface reservoirs tributary to the San Gabriel Valley on April 30, 2024 and April 29, 2025. Also shown are the current recorded inflow and outflow rates at the reservoirs on April 29, 2025. The total amount of local water stored in surface reservoirs in the San Gabriel Valley as of April 29, 2025, was about 36,800 acre-feet (about 35 percent of capacity), which is an increase of about 1,100 acre-feet in storage compared to April 30, 2024 (36,800 – 35,700). DPW indicates it maintains a minimum pool in Cogswell, San Gabriel and Morris Reservoirs representing about 10,500 acre-feet. Available stored water will be used to replenish groundwater supplies.

BASIN CONDITIONS - LOCAL AND IMPORTED WATER CONSERVED

The amount of local water conserved, which is typically the primary component of Basin replenishment, is dependent upon the amount of precipitation on the tributary watershed, resulting runoff, and the subsequent water replenishment activities of DPW. Historically, when the Basin experiences average to above-average precipitation, it results in a larger amount of local water available to replenish the Basin and the groundwater elevation increases. Examples of this relationship are shown on Figure 4 (see 1977-78, 1982-83, 2004-05, 2022-23 and 2023-24). The occurrence and duration of annual rainfall is also an important factor. For example, a large amount of rainfall over a short period of time may result in limited replenishment

to the Basin due to surface flows exceeding water replenishment capabilities and even result in flow of local runoff to the ocean. Also, rainfall that follows severe dry periods will often result in lower runoff amounts due to dry soil absorbing effects in the watershed.

Below normal rainfall in the Basin watershed so far during fiscal year 2024-25 has been about 45 percent of average through April 2025. Although DPW replenishment records are incomplete this time of year, preliminary data indicate approximately 23,700 acre-feet (about 23 percent of annual average) of local runoff was replenished in the Basin between October 1, 2024 and March 31, 2025. The average annual local water Basin replenishment has averaged about 110,000 acre-feet, prior to the recent long-term drought.

In addition, MWD began delivering imported water into the Basin (into MWD's Cyclic Storage account) in the spring 2025. Figure 1 includes a projection of the Key Well elevation assuming MWD delivers and replenishes 100,000 acre-feet in calendar year 2025 and the Basin experiences dry conditions.

Table 2 summarizes the annual rainfall, local water plus RDA II water and imported water replenished for Cyclic Storage and measured and operational groundwater elevations at the Key Well since the inception of Watermaster operations.

BASIN CONDITIONS - SUPPLEMENTAL WATER AVAILABILITY

Section 10 of the amended Judgment defines Supplemental Water as "Non-tributary water imported through a Responsible Agency." Upper District, Three Valleys Municipal Water District (Three Valleys District) and San Gabriel Valley Municipal Water District (San Gabriel District) are the Responsible Agencies which deliver Supplemental Water to the Basin. Upper District and Three Valleys District are member agencies of MWD. The San Gabriel District is a SWP contractor. The following describes the availability of Supplemental Water from MWD and San Gabriel District.

Metropolitan Water District of Southern California

MWD primarily receives its water supply from the State Water Project and the Colorado River. Below is a description of the availability of water from MWD.

Availability of Imported Water

An "8-station index" is used by the California Department of Water Resources (DWR) to determine average precipitation in the Sacramento River hydrologic region of northern California, which is the source of much of the imported water supply to the Basin. Through April 30, 2025, the "8-station index" indicated average precipitation of 54.2 inches or about 110 percent of average for that time of year, while rainfall in the San Gabriel Valley was about 45 percent of average (through April 30, 2025). This

indicates that even though the San Gabriel Valley is experiencing below average rainfall, Northern California's above average rainfall may increase the SWP Allocation to more than 50 percent and, consequently, more SWP water may be available to MWD and San Gabriel District for replenishment to the Main Basin.

On December 2, 2024, DWR announced the 2025 initial allocation of SWP water was 5 percent of the contractors' Table A Entitlement. On April 29, 2025, DWR announced the 2025 allocation of SWP water has increased to 50 percent of the contractors' Table A entitlement. As stated in DWR's Notice to State Water Project Contractors, the allocation is based on "projected 2025 demands, existing storage in SWP conservation facilities, estimate of future runoff..." In general, every five percent of SWP allocation equates to about 100,000 acre-feet of supply for MWD. With a 50 percent SWP allocation, MWD would receive about 955,750 acre-feet.

Based on the Colorado River Compact, the seven basin states receive allocations to Colorado River water. Based on California's allocation of Colorado River water, MWD staff has indicated about 939,000 acre-feet of Colorado River water are available to MWD during calendar year 2025. While Colorado River water can be delivered as Supplemental Water to help replenish the Basin, there are issues which must be addressed prior to delivery. Quagga mussels are in Colorado River water and have the potential to negatively impact the replenishment facilities unless the Colorado River water is isolated and the replenishment facilities are allowed to dry out, which effectively eliminates the Quagga mussels. A second concern is the high Total Dissolved Solids (TDS) concentration in Colorado River water, which would need to be addressed through Watermaster's "Criteria for Delivery of Supplemental Water". There are currently no planned deliveries of Colorado River water for Basin replenishment. However, MWD, Upper District and Watermaster have worked cooperatively on preparing a Provisional Quagga Mussel Control Plan to potentially deliver Colorado River water to the Basin as a last resort only if SWP water is not available and the Key Well is projected to reach emergency water levels.

San Gabriel District

San Gabriel District has a contract for State Water Project water (see description of State Water Project availability under MWD). San Gabriel District's current 2025 allocation is 50 percent of its State Water Project Table A entitlement of 28,800 acre-feet. Consequently, it is anticipated San Gabriel District will deliver about 14,400 acre-feet to the Basin during calendar year 2025.

Deliveries of Stormwater Augmentation Program Water (RDA II)

Section 45(b)(7) of the amended Judgment allows Watermaster to "...levy an Assessment on all Pumping, as determined through Rules and Regulations ... to support the purchase, financing, and/or development of new or additional Supplemental Water sources, in cooperation with one or more Responsible Agencies

as appropriate.” Section 45(b)(7) established the RDA for the purchase or development of additional Supplemental Water supplies.

As previously discussed, the “Stormwater Augmentation Program,” purchases available untreated imported water to supplement the shortage of local stormwater replenishment. The RDA II assessment is on all production and the purchased water is added to the natural Basin water supply, with no specific rights to recover the water. Production during fiscal year 2016-17 was the first year RDA II assessment was applied at \$40/AF. The RDA II assessment increased to \$175/AF on fiscal year 2020-21 and remained at \$175/AF every year through fiscal year 2024-25. For the eighth year, at \$175 on fiscal year 23-24 production of about 171,000 acre-feet, about 30,000 acre-feet was delivered during fiscal year 2024-25. Assuming fiscal year 2024-25 production is about 190,000 acre-feet and at \$175/AF, about 27,000 acre-feet could be purchased with RDA II assessment funds and be delivered during fiscal year 2025-26.

Deliveries of Supplemental Water

In addition to Basin replenishment from local water supply, the groundwater elevation at the Key Well is impacted by the amount of Supplemental Water delivered as Replacement Water, RDA Water and for Cyclic Storage accounts. A summary of historical Supplemental Water deliveries is shown on Table 5. The following sections describe Supplemental Water deliveries, as 1) Replacement Water for Upper District, San Gabriel District and Three Valleys District; 2) MWD Agreement water; 3) Producer and other Cyclic Storage accounts and 4) Future Deliveries.

Replacement Water

Section 42 of the amended Judgment states in part, "... Watermaster shall recharge Replacement Water in accordance with the Watermaster Operating Criteria and, insofar as practicable, to maintain the water level at the Key Well above Elevation two hundred (200)." (As of May 2, 2025, the groundwater elevation at the Key Well was 244.3 feet.) Typically, establishing a lower Operating Safe Yield results in reduced water rights, increased Replacement Water obligations and, consequently, increased deliveries and replenishment of imported water as Replacement Water. However, thus far, there is a lot of Cyclic Storage water in accounts, which can be deducted to meet Replacement Water obligations instead of delivering water to the Basin.

Estimated 2025-26 Supplemental Water Delivery Requirements - Replacement Water Plus Stormwater Augmentation Program Water

The estimated fiscal year 2024-25 over-production in the Basin is about 29,000 acre-feet, assuming production of about 190,000 acre-feet. It is assumed much of the over-production will be satisfied by a deduction from water in Producers' Cyclic Storage accounts.

Cyclic Storage Water

Cyclic Storage water is a pre-delivery of Replacement Water. Under the terms of Cyclic Storage agreements, the Individual Producers may make deliveries to Watermaster out of their Cyclic Storage accounts to satisfy Replacement Water requirements which are accounted for following June 30 of each year. The Responsible Agencies may make deliveries to Watermaster out of their Cyclic Storage accounts to satisfy Replacement Water requirements as of June 30 of each year.

There are Cyclic Storage agreements between Watermaster and each of the Responsible Agencies which provide for the total storage of up to 300,000 acre-feet of Supplemental (Replacement) Water in the Basin. This includes up to 50,000 acre-feet for San Gabriel District, up to 200,000 acre-feet for the MWD and Upper District, and up to 50,000 acre-feet for MWD and Three Valleys District. In addition, there are 21 producer Cyclic Storage agreements in which up to 175,525 acre-feet can be stored. The total amount of water that could be stored in existing Cyclic Storage accounts is up to 475,525 acre-feet. As of February 28, 2025 there was a total of about 170,000 acre-feet in Basin cyclic storage (represents about 21 feet at the Key Well).

Water in Cyclic Storage is available to supply Replacement Water by transfer to Watermaster in-lieu of physically delivering Supplemental Water. This is typically done at the discretion of the storing party. Table 3 is a summary of the monthly Cyclic Storage account balances since July 1, 2017. The storage balance in all of the Basin Cyclic Storage accounts on July 1, 2024, the balance as of February 28, 2025 and the estimated balance as of June 30, 2025, is shown below in acre-feet.

	Cyclic Storage as of July 1, 2024	Account Balance as of February 28, 2025	Estimated Balance as of June 30, 2025^{1/}
San Gabriel Valley Municipal Water District	2,571	3,473	15,000

1/ It is assumed Replacement Water requirements will be deducted from Cyclic Storage accounts following the end of fiscal year 2024-25. It is assumed 2025 SWP water allocation is 40 percent.

BASIN CONDITIONS - CARRY-OVER RIGHTS

In accordance with the Judgment Section 49, "...Any Pumper's Share of the Operating Safe Yield and the Production Right of any Integrated Producer, which is not produced in a given fiscal year, may be carried over and accumulated for one fiscal year..." Establishing high operating safe yields will normally result in increased Carry-over Rights. These Carry-over Rights must be used by the Producer in the next year or can be leased to another Producer for use in that year. The first water produced in the succeeding fiscal year is deemed to be the Carry-over water and therefore, unused production right will be carried over the following year, which increases Carry-over Rights every year. Leasing of water rights, including Carry-over Rights, also usually results in a reduction of the amount of water subject to Replacement Water assessments and, thus a decrease in delivery of Replacement Water to the Basin.

The amount of Carry-over Rights is considered when recommending the Operating Safe Yield. The Carry-over Rights at the beginning of fiscal year 2024-25 were approximately 35,000 acre-feet. It is estimated the Carry-over Rights at the beginning of fiscal year 2025-26 will be about 42,000 acre-feet assuming production of about 190,000 acre-feet. Historical Carry-over Rights and lost Carry-over Rights are shown on Table 1.

BASIN CONDITIONS - ESTIMATED WATER PRODUCTION DURING 2024-25

Historical water production under the Judgment since July 1, 1973, has been reported and recorded on a quarterly basis, as shown in Table 6. The preliminary total water production for the first two quarters of fiscal year 2024-25 was about 103,000 acre-feet. Figure 8 shows quarterly production in the Basin for the past 14 years (fiscal years 2011-12 through 2023-24) plus fiscal year 2024-25. Anticipated groundwater production for fiscal year 2024-25 has been estimated below.

The reported production for the first two quarters of fiscal year 2024-25 was about 103,000 acre-feet. This is similar to the first two quarters of fiscal years 2019-20 (103,000 acre-feet). Assuming production for the last two quarters of fiscal year 2019-20 is similar to the production for the last two quarters of fiscal years 2024-25, which was about 90,000 acre-feet, it is anticipated that the total fiscal year 2024-25 production will be about 190,000 acre-feet. Direct treated water deliveries have remained about the same, as described below. In addition, drought conservation activities have continued, which also have impacted production. Figure 8 shows production for the past 14 years and the estimated groundwater production for fiscal year 2024-25.

The historical total demand in the Basin is met by local water production and direct treated imported water deliveries. During fiscal year 2023-24, direct treated imported water sales were about 13,700 acre-feet, as shown in Table 7. Estimated direct treated imported water sales for fiscal year 2024-25 is about 19,000 acre-feet.

Total demand during fiscal year 2024-25 is estimated to be about 209,000 acre-feet (190,000 + 19,000) and is about 13,000 acre-feet below the 13-year average total water demand of 222,000 acre-feet, as shown in Table 7.

FISCAL YEAR 2024-25 OPERATING SAFE YIELD DETERMINATION

On May 1, 2024, Watermaster considered the Engineer's recommended Preliminary Operating Safe Yield of 160,000 acre-feet for fiscal year 2024-25. At that time, the total rainfall in the Basin from July 1, 2023 to April 30, 2024, as represented by the Puddingstone Dam station, was 23.88 inches or 136 percent of long-term average for that period. (The total annual rainfall at the Puddingstone Dam station for fiscal year 2023-24 was 24.15 inches, representing about 131 percent of average.) The groundwater elevation at the Key Well at the time of the May 2024 Watermaster meeting was 235.8 feet and increasing at the rate of about 3 feet per week. Total water in local storage reservoirs was 36,000 acre-feet.

At its May 1, 2024 meeting, Watermaster established the Operating Safe Yield at 160,000 acre-feet for fiscal year 2024-25 and an estimated Operating Safe Yield of 140,000 acre-feet for fiscal years 2025-26, 2026-27, 2027-28 and 2028-29.

CONCLUSIONS

It is very important to recognize that "local" water resources and supplies have been seriously impacted by unprecedented long-term drought conditions and the Key Well reached 177 feet in October 2022 and projected to reach the historical low of 169 feet in November 2022. However, fiscal years 2022-23 and 2023-24 have been unexpected above average rainfall years and helped raise water levels to a peak of 240 feet in June 2024, as shown in Figure 2. Now fiscal year 2024-25 has, so far, been below average rainfall, only 7.01 inches as of April 30, 2025. However, Northern California has been experiencing 93 percent of normal snowfall and 110 percent of normal rainfall. The SWP Allocation for 2025 is 50 percent, as of April 2025, and may still increase due to the rainfall and snowfall during February and March, and potentially April in Northern California. This indicates that even though the San Gabriel Valley is experiencing below average rainfall, Northern California's snowfall and above average rainfall may have more SWP water available to MWD and San Gabriel District for replenishment to the Main Basin.

Watermaster uses funds from Replacement Water/Cyclic Storage orders and RDA requirements from Upper District in order to purchase water from MWD's Pre-Delivery Agreement over 5 to 10 years. Currently, there are plans to deliver water in MWD's Cyclic Storage under the Pre-Delivery Agreement starting in the spring. With the increase in the SWP Allocation to 50 percent, MWD will be able to deliver water through the end of 2025 under the Pre-Delivery Agreement. To ensure funds are available each year, the OSY would need to be set in order to create a Replacement Water/Cyclic Storage requirement. However, if there is not enough funds from Replacement Water requirement, more RDA water would need to be purchased to

make up the difference. This is accomplished by increasing the RDA assessment. This is a way how both OSY and RDA are used as “tools” to manage Basin water levels and Basin storage.

As stated earlier in the Report, Section 42 of the amended Judgment states in part, “...Watermaster shall recharge Replacement Water in accordance with the Watermaster Operating Criteria and, in so far as practicable, to maintain the water level at the Key Well above Elevation two-hundred (200)”. The Judgment criteria essentially establishes the Operating Safe Yield and delivery of Replacement Water as the primary Watermaster tool to manage groundwater supplies for the Basin. This management goal became not “practicable”, as a result unprecedented local drought conditions, and resulted in the RDA II – Stormwater Augmentation Program. The Stormwater Augmentation Program has resulted in the important recovery of Basin water levels and an addition to Watermaster’s Basin management approach under Section 42, of the amended Judgment. The RDA II Program will likely continue to be an additional management tool for Watermaster until Basin water levels fully recover and demonstrate sustainability, and annual Replacement Water requirements reduce the large quantity of water held in Cyclic Storage.

Fiscal Year 2023-24 (Full Year) and Fiscal Year 2024-25 Comparison

<u>Last Year’s (FY 23-24) Condition</u>	<u>This Year’s (as of April) Condition</u>
Key Well June 30 th – 239.5 ft	Key Well – 244.3 ft
Rainfall – 24.15 inches	Rainfall – 7.0 inches
Local Runoff – 156,000 AF	Est. Local Runoff – 23,700 AF
SWP Allocation – 40%	Est. SWP Allocation – 50%
Engineer Rec. – 160,000 AF	Engineer Rec. – 160,000 AF
Watermaster Adopted – 160,000 AF	Watermaster Adopted – 160,000 AF

Based on the evaluation presented in this Report, the Engineer’s recommended Operating Safe Yield for fiscal year 2025-26 is 160,000 acre-feet and 140,000 acre-feet for the next four years.

ADOPTED OPERATING SAFE YIELD

On May 7, 2025, Watermaster held a hearing on the preliminary determination of Operating Safe Yield, which was submitted to Watermaster on April 2, 2025, in accordance with Section 43(a) of the Judgment. After review by its Engineer and comments received by those at the hearing, Watermaster approved the establishment of the Operating Safe Yield of the Main San Gabriel Basin at 160,000 acre-feet for fiscal year 2025-26, as shown below.

<u>Fiscal Year</u>	<u>Operating Safe Yield (Acre-feet)</u>
2025-26	160,000
2026-27	140,000
2027-28	140,000
2028-29	140,000
2029-30	140,000

Attached, as Appendix C, is a tabulation showing each Pumper's Share in percent and the number of acre-feet each Producer can produce from the Basin free of Replacement Water assessments for quantities of Operating Safe Yield 130,000 acre-feet per year to 160,000 acre-feet per year. Those producers shown to have a share less than five acre-feet prior to June 21, 2012 are Minimal Producers and are allowed to produce up to five acre-feet free of Replacement Water assessments.

San Dimas Dam	719	631	6	18	--	--
Puddingstone Dam ^{2/}	6,979	6,718	0	0	--	--
TOTALS:	35,723	36,806				

1/ Storage is typically zero. Reservoir used for Flood Control purposes only, not storage for water conservation purposes. As of May 2, 2025

2/ Storage is typically about 6,600 acre-feet. Used for recreational purposes, not water conservation purposes.
